

# Add Controller @RequestMapping

# Adding Request Mappings to Controller

- Serves as parent mapping for controller
- All request mappings on methods in the controller are relative
- Similar to folder directory structures

# Controller Request Mapping

```
@RequestMapping("/funny")
public class FunnyController {

    @RequestMapping("/showForm")
    public String showForm() {
        ...
    }

    @RequestMapping("/processForm")
    public String process(HttpServletRequest request, Model model) {
        ...
    }
}
```

The diagram illustrates the mapping of two methods in the `FunnyController` class to specific URLs. An orange callout box points from the `@RequestMapping("/showForm")` annotation to the URL `/funny/showForm`. Another orange callout box points from the `@RequestMapping("/processForm")` annotation to the URL `/funny/processForm`.
